possess all the properties of linear discrete-time systems discussed in Chapter 3. All linear discrete-time operations on an input sequence can be viewed as a filtering of the sequence to produce an output sequence.

A method for calculation probability stability of discrete-time control systems is given. In addition, for third order discrete-time control system is exactly determined probability stability. Formulas for estimated probability stability for arbitrary order discrete-time control systems are performed.

Discrete-time control systems differ from continuous-time control systems in that signals for a discrete-time control system are in sampled-data form or in digital form. If a digital computer is involved in a control system as a digital controller, any sampled data must be converted into digital data.

Discrete time views values of variables as occurring at distinct, separate "points in time", or equivalently as being unchanged throughout each non-zero region of time ("time period")—that is, time is viewed as a discrete variable. Thus a non-time variable jumps from one value to another as time moves from one time period to the next. This view of time corresponds to a digital clock that ...

Digital simulation is an inherently discrete-time operation. Furthermore, almost all fundamental ideas of signals and systems can be taught using discrete-time systems. Modularity and multiple representations, for example, aid the design of discrete-time (or continuous-time) systems. Similarly, the ideas for modes, poles, control, and ...

In control engineering, a state-space representation is a mathematical model of a physical system as a set of input, output and state variables related by first-order differential equations or difference equations. State variables are variables whose values evolve over time in a way that depends on the values they have at any given time and on the externally imposed values of input variables.
