In signal processing applications, it is the probabilistic description of the random variable, rather than the statistical characterization of events in the sample space, that is generally of interest. It is therefore more convenient to have a

A signal is classified as random if it takes on values by chance according to some probabilistic model. You can extend the

deterministic sinusoid model to a random model by making one or more of the parameters random. By introducing random parameters, you can more realistically model real-world signals.

Differing from a direct spectral-analysis approach, the authors claim that 'the only really careful way to describe noise is begin with a probabilistic description and then proceed to derive the associated spectral characteristics from the probabilistic model'
